INT-CL (IPC): C02F001/30

ABSTRACT:

PROBLEM TO BE SOLVED: To improve a water activation function without the generation of stagnation by a method in which, corresponding to the amount of raw water to be treated, at least two lines of hollow cylinders are formed in a water activation device, at least two pieces of a ceramic material are packed into the cylinder in a line in the water flow direction.

SOLUTION: In a water activation device 3 for ceramic treatment, raw water is supplied from a raw water supply port 1, after being dispersed by a porous plate 5, introduced into ceramic units 7, and brought into contact with a ceramic material 6 packed in the units 7, After that, again behind treated water discharge side porous plates 2-5, water ceramic-treated in each ceramic

unit 7 is combined, and discharged from a treated water discharge opening 2.

The connection number of the ceramic units 7 is made proportional to the amount

of treated water and not restricted in particular. In this way, by packing the

ceramic material 6 into the ceramic units 7 as a water activation device, water

to be treated is made to flow uniformly in each unit 7.
